# MAJOR PROJECT REPORT CUSTOMER CHURN PREDICTION

Name: Avinash R C

Group: 7

#### • Objective:

The objective of this project is to create a ML model for predicting the customer churn by taking use of the given 'train' and 'test' datasets.

#### • Tools Used:

- 1. Platform:
  - a. Jupyter Notebook
- 2. Language Used:
  - a. Python
- 3. Libraries:
  - a. Sci-kit learn
  - b. Matplotlib
  - c. Seaborn
  - d. Pandas
  - e. NumPy

#### • Dataset used:

- o Train.csv
- o Test.csv

## • Data Description:

- o The given dataset contains various attributes, which on the basis of those attributes and their relationships, a model has been created.
- The attributes are:
  - State
  - Account\_length
  - Area\_code
  - International\_plan
  - Voice\_mail\_plan

- Number\_vmail\_messages
- Total\_data\_minutes
- Total eve minutes
- Total\_eve\_charge
- Total\_night\_minutes
- Total\_night\_calls
- Total\_night\_charge
- Total\_intl\_minutes
- Total\_intl\_calls
- Number\_customer\_service\_calls
- Churn
- o From the above-named attributes, we can say their description i.e., these attributes represent a service provider data set. [e.g., Airtel, Jio].
- O This represents a customer database and information related to their usage of the service like number of calls made in night, day, voicemail usage etc.,
- Based on these data, a model must be created to predict the customer churn i.e., whether the customer wants to change the service/plans or not or in other words – 'The number of paying customers who fail to become repeat customers.

#### Approach:

 My approach for this project is on the basis of the following steps implemented to develop a model.

# Steps Involved

- o **STEP 1:** Importing the needful libraries
- o STEP 2: Uploading the 'train' dataset
- o **STEP 3:** Null-value check
- STEP 4: EDA and Visualisation
  - Pie charts, bar plot
  - Plotting the state wise customers according to churn outcome.
- o **STEP 5:** Correlation matrix and heatmap
- STEP 6: Feature Engineering
- o **STEP 7:** Developing a Model
  - Random-Forest Classifier
  - Accuracy detection using **F-Score**
- o **STEP 8:** Dimensionality Reduction
- o **STEP 9:** Uploading the 'test' dataset
- o **STEP 10:** Testing the 'test' dataset using the model developed
- STEP 11: Conclusion

#### • Explanation of the Steps Used:

#### • STEP 1: Importing the needful libraries

- This is the first step of any ML problems.
- Importing the necessary libraries for imparting EDA, pre-processing, regression .... etc., to develop a Model.

```
Importing the Libraries

In [139]: import pandas as pd import numpy as np import matplotlib.pyplot as plt import seaborn as sns from sklearn.model_selection import train_test_split from sklearn.model_selection import cross_val_score from sklearn.metrics import f1_score,confusion_matrix from sklearn.metrics import accuracy_score
```

#### • STEP 2: Uploading the 'train' dataset

• Here, we upload the 'train' dataset that we are going to use for the further process i.e., using this dataset a model is created.

de - nd	s = pd.read csv('C:/Users/rcavi/Desktop/major project/train.csv')												
. us - putreau_csv( c./users/reavi/besktop/major project/train.csv )													
ds													
l_eve_char	ge total_night_minutes	total_night_calls	total_night_charge	total_intl_minutes	total_intl_calls	total_intl_charge	number_customer_service_calls	chui					
16.	52 254.4	103	11.45	13.7	3	3.70	1						
10.	30 162.6	104	7.32	12.2	5	3.29	0						
5.	26 196.9	89	8.86	6.6	7	1.78	2						
12.	51 186.9	121	8.41	10.1	3	2.73	3						
29.	32 212.6	118	9.57	7.5	7	2.03	3						
20.	72 213.7	79	9.62	10.3	6	2.78	0						
11.	15 186.2	89	8.38	11.5	6	3.11	3						
16.	41 129.1	104	5.81	6.9	7	1.86	1						
18.	96 297.5	116	13.39	9.9	5	2.67	2	r					
22.	70 154.8	100	6.97	9.3	16	2.51	0						

#### • STEP 3: Null-value check

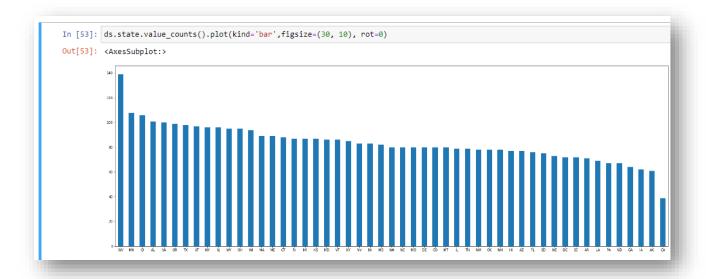

- This step is to be done before proceeding to pre-processing and EDA
- It is done to check for any null-values or empty cells in the given dataset which are not needed for processing.
- Their presence may lead to some hindrance while proceeding with visualisation.

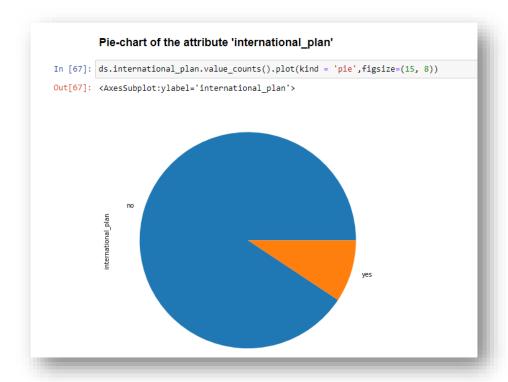

```
Checking for null-values
In [8]: #Confirm the number of missing values in each column.
         ds.info()
         <class 'pandas.core.frame.DataFrame'>
         RangeIndex: 4250 entries, 0 to 4249
         Data columns (total 20 columns):
                                                  Non-Null Count Dtype
         # Column
          0 state
                                                 4250 non-null object
          1 account_length
                                                4250 non-null int64

4250 non-null float64
          10 total_eve_calls
                                               4250 non-null
4250 non-null
                                                                  int64
          11 total_eve_charge
                                                                   float64
          12 total_night_minutes
                                               4250 non-null float64
                                               4250 non-null int64
4250 non-null float64
          13 total_night_calls
          14 total_night_charge
          15 total_intl_minutes
                                                4250 non-null
                                                                  float64
          16 total_intl_calls
17 total_intl_charge
                                                4250 non-null
                                                                   int64
float64
                                                 4250 non-null
          18 number_customer_service_calls 4250 non-null
                                                  4250 non-null
          19 churn
                                                                  object
         dtypes: float64(8), int64(7), object(5)
         memory usage: 664.2+ KB
```

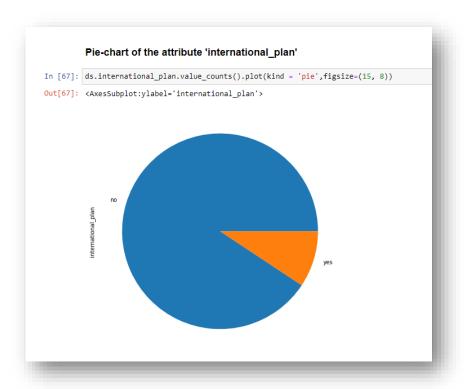

#### • STEP 4: EDA and Visualisation

• EDA is the process of analysing the given data for finding some useful relationships between the dataset, useful patterns, statistical representation, mean, median, finding any outliers etc.,

• In this step, we used Bar-plot representation using 'seaborn' library for analysing the data and pie-chart for representing % of data to check its majority

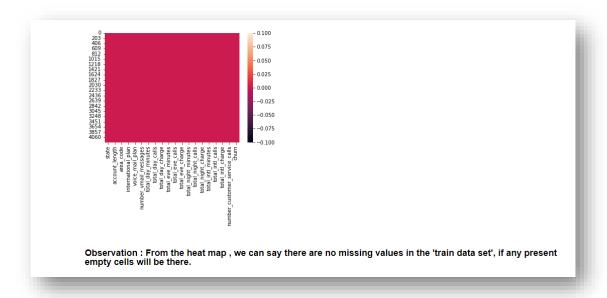

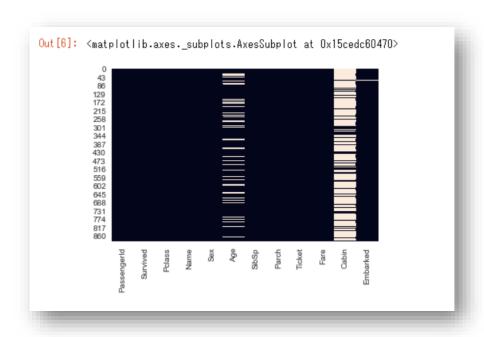

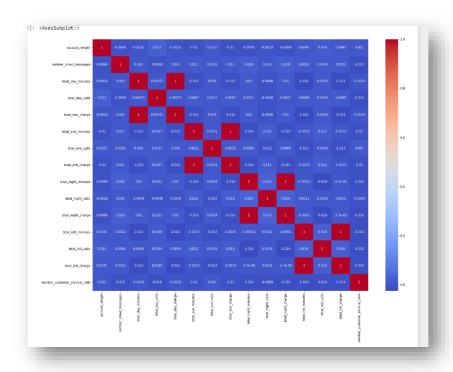

# • STEP 5: Correlation matrix and heatmap

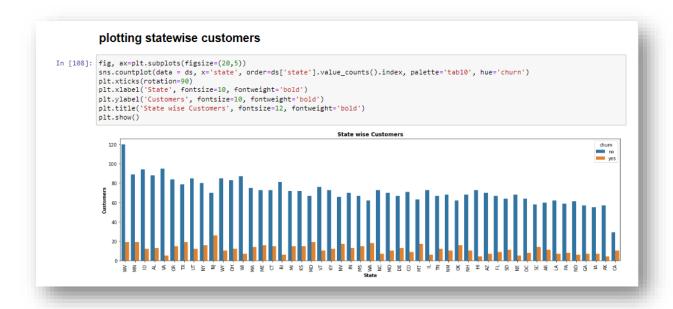

- Step 5 is a sub-part of step 4 A <u>correlation matrix</u> is simply a table which displays the correlation coefficients for different variables.
- It is a powerful tool to summarize a large dataset and to identify and visualize patterns in the given data.
- A heatmap contains values representing various shades of the same colour for each value to be plotted. Usually, the darker shades of the chart represent higher values than the lighter shade.
- The observation of the visuals is mentioned in the below mentioned diagrams.
- The below 'red' heatmap shows that there are no missing values present in the dataset.
- Else, they will be missing part depicting missing values in the heat map.

# Example of 'heat-map with missing values'

# • STEP 6: Feature Engineering

- <u>Feature engineering</u> is the pre-processing step of machine learning, which is used to transform raw data into features that can be used for creating a predictive model using Machine learning or statistical Modelling.
- It aims to improve the performance of models.
- Here, we have created columns for rate of calls, so call charge columns could be dropped as they are corelated.

```
In [129]: X0.drop({'voice_mail_plan'},axis=1,inplace= True)
In [130]: X0.isnull().sum().any()
Out[130]: False
In [131]: X0.isnull().sum().any()
Out[131]: False
```

# • STEP 7: Developing a Model and Accuracy using F-Score

- This part of the step gives us the desired output.
- It is the most important of any ML/ Data science problems
- It is a process in which a machine learning (ML) algorithm is fed with sufficient training data to learn from.
- Here we used 'Random-Forest' classifier for developing a model

#### • Random Forest

- Random Forest is a classifier that contains a number of decision trees on various subsets of the given dataset and takes the average to improve the predictive accuracy of that dataset.
- Instead of relying on one decision tree, the random forest takes the prediction from each tree and based on the majority votes of predictions, and it predicts the final output.
- The greater number of trees in the forest leads to higher accuracy and prevents the problem of overfitting.

# F-Score In [104]: fscore=f1\_score(y\_valid,clf\_rf.predict(X\_valid),average='micro') fscore=fscore\*100 print(f"Accuracy of the model using F-Score is {round(fscore,2)}") #'micro': #Calculate metrics globally by counting the total true positives, false negatives and false positives. Accuracy of the model using F-Score is 92.54 Accuracy of the model is 92%

## • STEP 8: Dimensionality Reduction

- Dimensionality reduction simply refers to the process of reducing the number of attributes in a dataset while keeping as much of the variation in the original dataset as possible
- This process can be classified into two ways:
  - Feature Selection (χ2 test)
  - o Feature Extraction

#### • Advantages:

- A lower number of dimensions in data means less training time and less computational resources and increases the overall performance of machine learning algorithms
- o Dimensionality reduction is extremely useful for data visualization
- Here, we have used  $\chi 2 test$  for dimensionality reduction.
- A  $\chi 2$  test is basically a data analysis on the basis of observations of a random set of variables. Usually, it is a comparison of two statistical data sets.

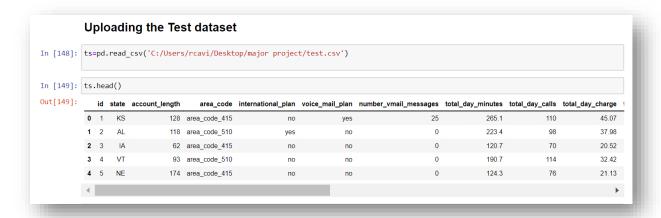

```
In [142]: from sklearn.feature_selection import SelectKBest
          from sklearn.feature_selection import chi2
# find best scored 5 features
select_feature = SelectKBest(chi2, k=5).fit(X_valid, y_valid)
          a = select_feature.scores_
          b = X train.columns
          df = pd.DataFrame(list(zip(b, a)),
                       columns =['Column', 'Score'])
          df.dtypes
Out[142]: Column
                   object
          Score
                    float64
          dtype: object
Out[144]:
                              Column Score
           2 total_day_minutes 398
            1 number_vmail_messages
                 total_eve_minutes
           67
                    international_plan_yes
           10 number_customer_service_calls 52
           22
                              state_DE
           21
                              state_DC
           19
                              state_CO 0
           47
                              state NV
           34
                              state_MD
          68 rows × 2 columns
```

# • STEP 9: Uploading the 'test' dataset

&

# STEP 10: Testing the 'test' dataset using the model developed

- Now, we have to test the model we developed using the 'test' dataset
- For that, we'll make predictions for the first few rows of the test data to see how the predict function works.

```
In [70]: submission = pd.DataFrame({
        "id": ts["id"],
        "churn": results
})
submission.to_csv('churn_output.csv', index=False)
```

```
In [76]: churn_output.shape
Out[76]: (750, 2)
```

#### • STEP 11: Conclusion

- The used **Random Forest Classifier** for our model gives the accuracy of 92 % when detected using **F-Score** which is a great result for a ML model.
- So, after pre-processing and EDA techniques, the model developed using **Random Forest** is apt for the given Customer Churn Prediction.
- After testing the model using the 'test.csv' dataset, the 'churn\_output.csv' is the final output of whether the customer churn is positive or negative.

• Sample – 'churn\_output.csv'
